INTRODUCTION

This City Pack provides high level, non-technical summaries of climate change projections for an individual city or town. It uses scientific research to provide robust climate information to help decision makers plan for the future, enabling cities and towns to become more resilient to climate change.

Urban areas experience unique challenges from climate change. For example, urban environments contain surfaces which don’t soak up and store rainfall, such as tarmac and paving, which might increase flood risk. Urban areas are also affected by the urban heat island effect, which results in higher urban temperatures compared with surrounding rural areas.

WHAT AFFECTS THE REGION'S WEATHER?

Newcastle is located within the North East of England, which includes the counties of Northumberland, Tyne and Wear, Durham and North, West and South Yorkshire. Here are some of the types of weather the region experiences across a year:

- Temperatures throughout the year in the North East of England are cool due to the relatively cold waters of the North Sea and also the extensive upland areas. In low-lying areas, where most urban areas are found, mean annual temperatures are around 10°C.

- Average annual sunshine hours over North East England range from over 1500 hours on the coast to less than 1250 hours in the higher Pennines.

- Rainfall is highly variable across the North East of England, exceeding 1500 in the Pennines compared to 600 mm in populous places such as Tees-side. Rainfall is greatest in autumn and winter with the passage of Atlantic depressions, although towards the coast this becomes more balanced by summer showers.

- On average, the number of days with snow falling is about 20 per year near the coast and in low lying areas of South Yorkshire and about 50 days over the higher Pennines. Exposure to northerly winds increases the likelihood of snowfall, which can be showery in nature as cold airstreams pass over the North Sea.

HOW HAS NEWCASTLE’S CLIMATE CHANGED?

The stripes show how temperatures in Newcastle have increased, with many of the hottest years occurring in the last few decades.
OBSERVED CHANGES
How are temperature and rainfall changing across the UK?
These maps show changes in temperature (left) and rainfall (right) from 1991-2020 compared to a baseline period of 1961-1990. We can see that temperatures have risen in all areas across the UK. We can also see that whilst some areas have become drier, more areas have become wetter.

IMPACTS
Cities and towns across the UK are already experiencing the impacts of climate change. The negative impacts of climate change for urban areas may include:

- **HEAT**: Increased energy demand for summer cooling
- **SEA LEVEL RISE**: Increased risk of coastal flooding
- **HEAVY RAINFALL**: Increased risk of river and surface water flooding
- **DROUGHT**: Risk to water supplies from drought
- **DRAINAGE**: Increased disruptions to urban drainage system
- **ENVIRONMENT**: Increased risk to biodiversity (plants and animals)
- **ENERGY**: Infrastructure such as gas pipes are at high risk from flooding events.

FUTURE HEADLINES
The climate is already changing, and we are already seeing impacts. But how might the UK’s climate change in the future? The statements below are headline statements from the UK Climate Projections – cutting-edge climate science which provide an up-to-date assessment of how the climate is expected to change in the future:

- There is an increased chance of **warmer, wetter winters and hotter, drier summers**.
- Hot summers are expected to become more common. By 2050, every other summer may be as hot as the record breaking summer of 2018.
- Although the trend is for drier summers in the future, there may be increases in the intensity of heavy summer rainfall events.
- Sea level will continue to rise in the 21st century even if greenhouse gas emissions are reduced rapidly.
PROJECTIONS USED IN THE CITY PACK

The City Pack uses the UK Climate Projections (UKCP) Probabilistic Projections at 25 km resolution. The projections are provided as a ‘range’:

- The first number in the range, is the median (50th percentile) result from RCP 4.5 (MEDIUM emission scenario).
- The second number in the range is from RCP 8.5 (HIGH emission scenario) and shows a more extreme result (90th percentile, except for summer rainfall rate which uses the 10th percentile, representing drought conditions).

EMISSIONS SCENARIOS

Our future climate is determined by ongoing and future greenhouse gas emissions, which are uncertain. To capture this uncertainty, we use emissions scenarios, such as the Representative Concentration Pathways (RCPs).

RCPs describe possible future emissions based on assumptions about human activity.

The RCP pathways represent a broad range of possible futures and are neither forecasts nor policy recommendations.

This map shows the location of Newcastle and the area in focus for this City Pack. Projection information provided within this City Pack is calculated as the average (mean) value across the smaller inset box (a 25 km grid cell).

This box may include rural, coastal and mountainous areas as well as urban areas. As such, results for point locations within the grid box may differ from the average result of the box.

At 25 km resolution, detailed urban effects are not represented in the model. For urban representation, a higher resolution model is required. The use of UKCP Local (2.2 km) may be more appropriate.
GLOBAL WARMING LEVELS

<table>
<thead>
<tr>
<th>Global Warming Level</th>
<th>Time Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>4°C</td>
<td>2065 to 2100+</td>
</tr>
<tr>
<td>2°C</td>
<td>2031 to 2056</td>
</tr>
</tbody>
</table>

Global warming levels tell us about future temperature change at the global scale. What about at changes at the local scale?

### Results are calculated as change from the baseline period: 1981-2000.

**Summer Average Air Temperature (°C)**
- 2030s: +0.9 to +1.8
- 2050s: +1.4 to +3.1
- 2080s: +2.4 to +6.0

**Summer Maximum Air Temperature (°C)**
- 2030s: +0.8 to +2.0
- 2050s: +1.4 to +3.4
- 2080s: +2.6 to +6.8

**Winter Average Air Temperature (°C)**
- 2030s: +0.7 to +1.6
- 2050s: +1.0 to +2.5
- 2080s: +1.5 to +4.3

**Winter Minimum Air Temperature (°C)**
- 2030s: +0.7 to +1.8
- 2050s: +1.1 to +2.8
- 2080s: +1.7 to +5.0

**Annual Average Air Temperature (°C)**
- 2030s: +0.7 to +1.5
- 2050s: +1.1 to +2.4
- 2080s: +1.9 to +4.5

**Summer Precipitation Rate (%)**
- 2030s: +0 to -18
- 2050s: -7 to -28
- 2080s: -17 to -47

**Winter Precipitation Rate (%)**
- 2030s: +7 to +21
- 2050s: +8 to +27
- 2080s: +13 to +47

**Sea Level Change (m)**
- 2030s: +0.10 to +0.15
- 2050s: +0.19 to +0.31
- 2080s: +0.34 to +0.64

1st number in the range is RCP4.5 at the 50th percentile. 2nd number in the range is RCP8.5 at the 90th (except summer rainfall, which is the 10th percentile), calculated from UKCP 25 km Probabilistic Projections.

Results show changes in variables averaged over a season, and as such do not represent possible extreme conditions. For assessment of possible extremes, the use of UKCP Local (2.2km) may be more appropriate.
The risk posed from a changing climate, and the potential for resultant impacts, depends on three key factors:

HAZARD: weather and climate events which may have adverse effects. The occurrence, duration and intensity of which may change due to climate change.

EXPOSURE: the location of people, property and other economic resource, relative to a hazard.

VULNERABILITY: the likelihood of the exposed people, property and other economic resources suffering adverse effects from the hazard. Vulnerability is in turn affected by the capacity of people and places to adapt or respond to the hazard.

Following COP26, limiting warming to below 1.5°C above pre-industrial levels remains possible but will require bigger emission reductions than currently pledged by nations around the world. Current emission reduction pledges, made as part of nationally determined contributions, are likely to lead to warming above 2°C.

The Paris Agreement says that we must limit global warming to well below 2°C, whilst aiming for 1.5°C.

Without global action to limit emissions, we may exceed even 4°C of global warming.

To achieve Net Zero, and also prepare for the impacts of climate change, to which we are already committed, both mitigation and adaptation approaches are required.

Adaptation and mitigation both help to reduce the risk a city will face from climate change. Mitigation will help to limit the hazard, whilst adaptation can help to reduce exposure and vulnerability.
If anyone would like to provide feedback or discuss the factsheets further with a member of the Urban Climate Services team, we can be contacted via email at: urbanclimateservices@metoffice.gov.uk

This work was supported by the UK Research & Innovation (UKRI) Strategic Priorities Fund UK Climate Resilience programme. The programme is co-delivered by Met Office and NERC on behalf UKRI partners AHRC, EPSRC, ESRC.
